

# Lessons Learned

Robert Wilson  
U. S. Department of Energy

# Lessons from Idaho

- ▶ Essential CSP elements includes
  - ▶ Understand and documenting the NCS risk
  - ▶ Mechanisms for controlling the risk
- ▶ However, at the program I inherited in Idaho
  - ▶ Criticality staff provided modeling and calculations.  
(My focus was improving the calculation capability)
  - ▶ Upset conditions largely provided by the Plant Safety Document staff.
  - ▶ Criticality staff developed numeric limits and controls.

# 1978 Accident

- ▶ Basic criticality control in first cycle extraction was chemical processes to limit the uranium concentration in vessels and pipes.
- ▶ Controls were administrative (procedures)-aided by measurement devices.
- ▶ A 1978 accident illustrated serious flaws in the hazard assessment and control system.
  - ▶ Hazard Assessment -
    - ▶ Effect of the chemical dilution of scrub steam (direct cause) was documented but not the failure mode which caused the accident
  - ▶ Control
    - ▶ Correct operational procedures not used.
    - ▶ One measurement device was inoperative.
    - ▶ A second device, on plant controlled drawings, had not been installed.
    - ▶ Operators did not notice or respond to abnormalities.

# Program Upgrades Necessary

- ▶ Hazard Assessment
  - ▶ Use solvent extraction process chemical effects computer code to assess chemical risks
  - ▶ Use HAZOP method to define failure modes in the operations of chemical processes
- ▶ Controls Development and Implementation
  - ▶ Structured controls
    - ▶ Failure Limit, Safety Limit, Limiting Condition for Operations
      - ▶ Limits to provide basis to respond to non-conformance
    - ▶ Equipment relied on: classification/inspection criteria
  - ▶ Training for operators/tied to pay scale
  - ▶ Auditing for compliance improved
  - ▶ Configuration and Document control improved

# Value of competent Criticality Safety Programs

- ▶ I knew about Personnel Protection
  - ▶ We attribute a high value to human life
- ▶ I learned the Mission and Financial Impact
  - ▶ Even non fatal criticality accidents will significantly effect our facility
  - ▶ 1978 Idaho accident shut down plant for two years (mission loss) and cost a large part of a billion dollars

# More Idaho Lessons

- ▶ Fuel element pile found outside the unirradiated fuel storage building
  - ▶ We provided CSE for storage rack (Cd lined)
  - ▶ Also CSE for processing fuel elements
  - ▶ No CSE for transporting elements between facilities had been requested
  - ▶ Gaps need to be questioned
- ▶ During a fissile inventory, vials of Uranium Oxide removed from Cd lined racks and put by accountability staff in large garbage bag
  - ▶ Other groups than Operations need training and controls

# Yet More Idaho Lessons

## History

- ▶ A process campaign involving hundreds of kilograms ended, and an apparent discrepancy between input and output uranium mass values. The plant stopped.
- ▶ After several weeks of assessing the measurement data, statisticians determined the deviation was within measurement error and we could proceed with operations.
- ▶ Years later an unused and isolated cell was being prepared for demolition and measurement were made in large tanks.
- ▶ Measurement showed a uranium concentration about 12 g/l, (reported to me at 2:00 AM)
- ▶ We found the uranium discounted previously and an investigation found the path into the isolated cell.

## Lesson

- ▶ Accountability controls oft concern with deviations of large numbers.
- ▶ NCS concerns with smaller amounts on large places.
- ▶ Accountability concerns not the same as NCS concerns.

# More Idaho Lessons Yet

- ▶ Pathfinder Fuel Bucket Event
  - ▶ Routine NCS inspection of fuel storage basin noticed seven buckets, normally suspended two feet apart on rails, jackstrawed on basin floor.
  - ▶ Safety basis assumption was a maximum of two in contact

# Found Array of Fuel Buckets

# How to respond?

- ▶ NCS developed calculations to support recovery.
- ▶ Fuel was cylindrical with a central core poisoned with B4C.
- ▶ Calculations, using the fuel Processing Contract information, showed an infinite number of fuel elements would not go critical. We reasoned that this was unlikely for a reactor.
- ▶ The fuel shipper had not retained records of fuel details- I tracked down the chief startup engineer-who had retained fuel details in his basement.

# Pathfinder continued

- ▶ The reprocessing contract listed the amount of  $B_4C$  in the core was substantially more than the reactor startup records .
- ▶ 77 of the fuel elements had the poisoned core removed
- ▶ The minimum critical number of elements was a fraction of the pile observed.
- ▶ Strips of cadmium were hand inserted in each of the buckets and recovery was completed.
- ▶ Lessons Learned
  - ▶ Shipper's attention to his waste stream does not receive attention paid to product stream.
  - ▶ Events determined to be incredible, like seven jackstowed buckets, periodically happen

# More Idaho

## 1981 Decon Sink Event

- ▶ End of a production campaign which included converting uranium solution to  $UO_3$  in a denitrator
- ▶ Process began to flush the plugged denitrator
  - ▶ Many nitric acid flushes
  - ▶ New supervisor removed bottom plenum and delivered it to the Decontamination Facility
- ▶ Item placed in large sink and filled with 200 l of Nitric acid
  - ▶ Technician noticed acid had become greenish yellow
  - ▶ Sample taken - 7.1 g/l U

# Denitrator Room Layout

# Response to Event

- ▶ I was called at midnight
  - ▶ Informed dissolving  $\text{UO}_3$  was adding to the 7 g/l in the 200 l solution
  - ▶ Replied that some 20 g/l could result in a criticality
- ▶ Decon facility evacuated
- ▶ NCS worked all night and next day to gather info on plenum volume and  $\text{UO}_3$  density
  - ▶ Sink modeled with 4 kg in solution in 4 M acid and max  $k_{\text{eff}}$  was 0.86
  - ▶ Solution removed by entering facility and opening sink drain with long handled tool

# Lessons Learned

- ▶ Decontamination facilities need more attention
  - ▶ Facility added as Criticality Control Area
  - ▶ Staff and supervision need NCS training
- ▶ Proper information needs to be supplied from sending group to receiving group
  - ▶ New Requirement : two assessments of fissile content need to accompany transfers.

# Idaho Lessons-continued

## Protecting the program

- ▶ The contractor suffering the 1978 accident supported all reforms of the criticality safety program
- ▶ The resulting program was strong and effective.
- ▶ However, the initial contractor lost the contract due to the accident
- ▶ Each subsequent contractor questioned program elements not seen elsewhere
- ▶ Eventually we needed to fully describe the whole program in a manual. It was reviewed and approved by senior management and delivered to each operational unit
- ▶ Practices deemed important need to be broadly agreed to and formalized.

# Lessons from Colorado

## Issues in late 1990s

- ▶ NCS program turmoil;
  - ▶ Persistent NCS manager and staff turnover
- ▶ NCS staff experienced hostility from Operations
  - ▶ Staff faced resistance getting information for evaluations
  - ▶ When evaluation about done, learned operation had changed
  - ▶ Evaluations considered a permissive to operate
  - ▶ Compliance with controls was faulty
- ▶ Competent Evaluations were problematic

# Colorado Lessons continued

Core problem - Communication and cooperation

Action - Redefine the NCS program

Method - Develop a Program Manual

- ▶ Development team
  - ▶ Operations Management
  - ▶ NCS staff
  - ▶ Nuclear Safety staff
- ▶ Assessment team to critique result
  - ▶ Other operations groups
  - ▶ Union
  - ▶ Regulator
  - ▶ Outside independent NCS specialists

# Manual Features

- ▶ Chapters on all features of a mature program
- ▶ Most helpful provision
  - ▶ Criticality Safety Officer
    - ▶ Reports to Operations manager
    - ▶ Sets priorities for NCS staff facility tasks
    - ▶ Provides information conduit for evaluation development
    - ▶ Approves the evaluation for Operations
    - ▶ Develops implementation plan for controls
    - ▶ Coordinates task specific operations NCS training
    - ▶ Manages non-conformance responses

# CSO position results

## Benefits

- ▶ Higher quality Evaluations
- ▶ More thoughtful control implementation
- ▶ Better understanding of Operators of control purpose and implementation methods
- ▶ Fewer non-compliances
- ▶ Less frustration of NCS staff and fewer turnovers

## Other Responses

- ▶ Facility managers praised the concept and added additional CSOs
- ▶ Assessment teams took the concept elsewhere

# Conclusion

## Robust NCS Program

- ▶ Competent, involved NCS staff (low turnover)
- ▶ Good use of Hazard Assessment Methods
- ▶ Well defined and user friendly limits & controls
- ▶ Administrate the Evaluation assumptions also
- ▶ Assure Operations owns the NCS controls
- ▶ Strong Conduct of Operations program
- ▶ Operations staff with a questioning attitude
- ▶ Process to respond thoughtfully to non-conformances
- ▶ NCS group self critical culture

# Further Conclusion

- ▶ All sites need to solve actual and local issues as well as comply with Industry and government regulations.
- ▶ Both Idaho and Colorado NCS programs, before reforms, believed they had implemented all industry and government regulations; however, they were not effective programs.
